Meeting notes:

Config file:
- make it
- every chat with dataset and new names

how do we get the datasets:
- do they have to know the name?
- retrieve them from the API

- example datasets and dashboards in the superset repo
- cli tool for creating a superset account -> load examples into the instance
    - have those examples to use
    - not have multiple datasets with the same schema in the way that UNICEF uses it
    - generate some synthetic ones
    - dashboard with one or two charts -> enough to test the functionality
    - world bank and baby names dataset
        - has a time axis -> can be split into decades
        - turn one example dataset into many
        - close to UNICEF use cases

- how to check if dataset is viable:
    - superset keeps track of the schema
    - retrieve the schema from API
    - compare the templates from the

- cloning across instances
    - configuring the dashboard in staging, promote it to production instance
    - same operation
    - datasource might have same name but diff on production instance
    - across instance

    - different host name for the API endpoints
    - same API credentials, hot name, IP address
    - across instance —> creating the dashboard configurations on production instance
with the kenya datasource
    - two different host names or IP address
    - same API calls retrieved in staging

- dashboard you want to clone that has a datasource

- destination might be on the same instance or different instance
    - config file —> specify what the available instances
    - save host name and IP address for each instance
    - store the username and password
    - select the instance before selecting the new datasource
        - datasources are specific to the instance
- a new name

access to superset instance hosted on the cloud with sample data
- he can do it yay
- can get some example datasets
- can maybe get it done
- has an old version on a venv that he can try to give us access to
